Lecture 02: Processes and Threads

CS343 – Operating Systems

Branden Ghena – Fall 2022

Some slides borrowed from:
Stephen Tarzia (Northwestern), Jaswinder Pal Singh (Princeton), Harsha Madhyastha (Michigan), and UC Berkeley CS61C and CS162

Administrivia

- Getting Started Lab
  - Due on Tuesday next week
  - Purpose is to make sure that you've got everything set up right
    - SSH login for EECS servers
    - Github account and Git SSH access
    - Ability to build the Nautilus Kernel
  - Let us know if you're having problems with this
    - Should not take long to complete
    - 43/80 of you have at least made your own repo (most are done)

Administivia part 2

- Campuswire
  - Everyone should have access to it
  - If you don’t, this is an exception when you should email me

- Canvas
  - Most important information is on the Canvas homepage
  - I post slides there too before each class

Today’s Goals

- Understand the operating system’s view of a process.
- How does a process communicate with the OS?
- Explore a few process creation system calls.
- What are threads and why are they useful?

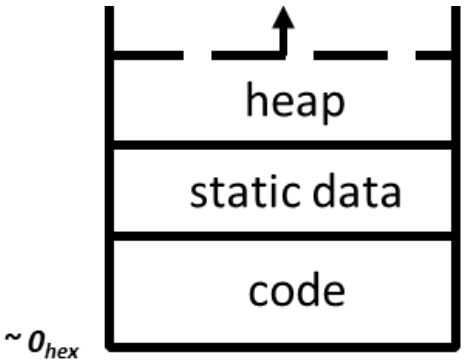
Outline

- **Processes**
- System Calls
- Process Creation
- Signals
- Threads

View of a process

- Process: program that is being executed
- Contains code, data, and a thread
  - Thread contains registers, instruction pointer, and stack

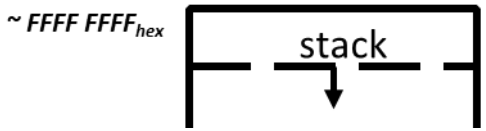
- Code and Data



- Registers

%rax	%eax	%r8	%r8d
%rbx	%ebx	%r9	%r9d
%rcx	%ecx	%r10	%r10d
%rdx	%edx	%r11	%r11d
%rsi	%esi	%r12	%r12d
%rdi	%edi	%r13	%r13d
%rsp	%esp	%r14	%r14d
%rbp	%ebp	%r15	%r15d

- Instruction Pointer
- Condition Codes
- Stack



POSIX processes also have file descriptors

- Integers specifying a file the process is interacting with
  - Process contains a table linking integers to files (and permissions)

- Default file descriptors
  - 0 - Standard input (stdin)
  - 1 - Standard output (stdout)
  - 2 - Standard error (stderr)

- Function calls to interact with files
  - `int open (const char *path, int oflag, ... );`
  - `ssize_t read (int fildes, void *buf, size_t nbyte);`
  - `ssize_t write (int fildes, const void *buf, size_t nbyte);`

Example file descriptors

```
[brghena@ubuntu northwesternos.github.io] [master] $ lsof -p 6447
COMMAND  PID    USER   FD   TYPE DEVICE SIZE/OFF    NODE NAME
vim     6447 brghena  cwd    DIR    8,5     4096  524310 /home/brghena/Dropbox/class/cs343/northwesternos.github.io
vim     6447 brghena  rtd    DIR    8,5     4096       2 /

vim     6447 brghena    4u   REG    8,5    16384  524588 /home/brghena/Dropbox/class/cs343/northwesternos.github.io/.index.html.swp
```

Additional process contents

- Whatever else the OS thinks is useful
  - Process ID
  - Priority
  - Time Used
  - Process State

- Different OSes will attach different things to the "process abstraction"

Processes are an abstraction provided by the OS

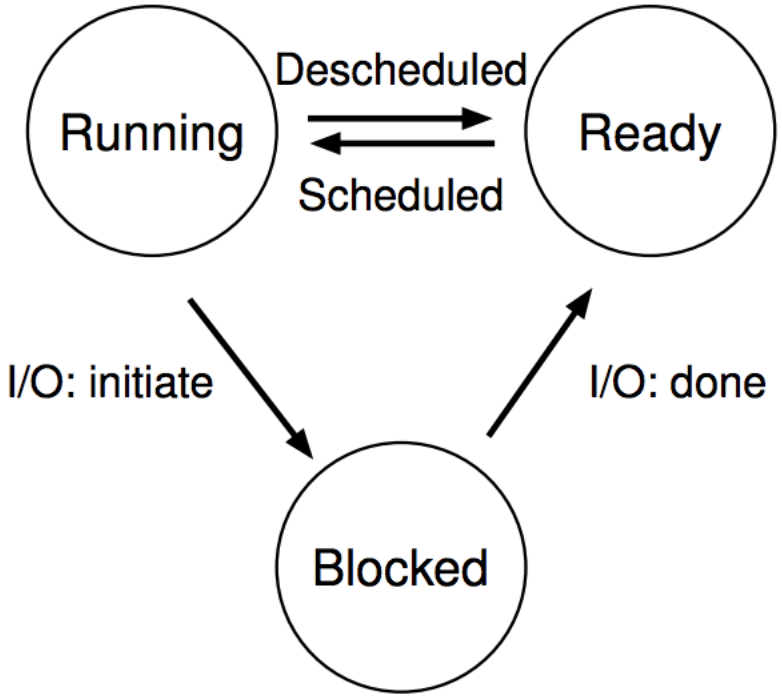
- The machine itself usually doesn’t support processes
  - Just has a processor and a set of registers
  - Memory is just arbitrary memory

- OS provides the abstraction
  - Multiple processes can run at the “same time”
  - Each has its own registers
  - Each has its own isolated memory

- Processes enable
  - Multiple functionalities on a computer
  - Multiprogramming of a system

Processes don’t run all the time

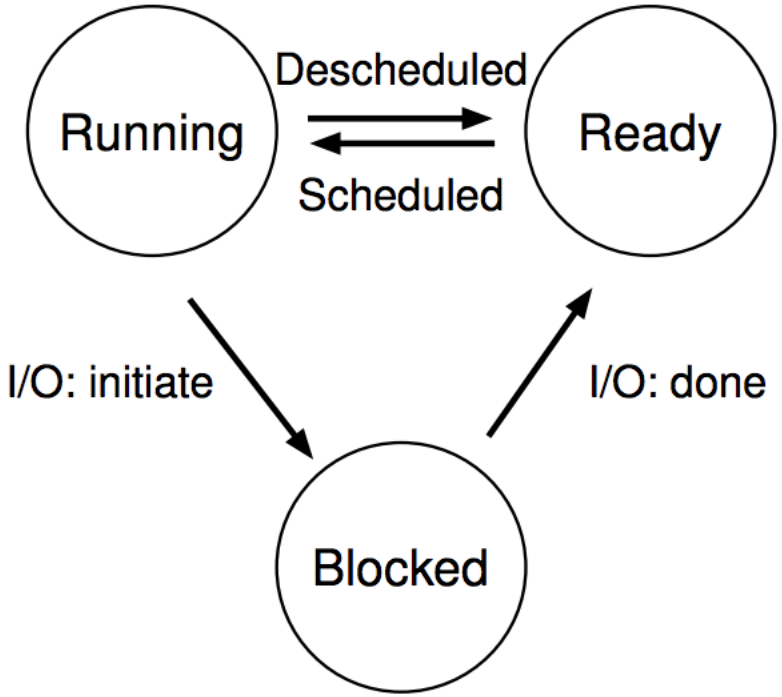
The three basic process states:



- OS ***schedules*** processes
  - Decides which of many competing processes to run.
- A ***blocked*** process is not ready to run.
- I/O means input/output – anything other than computing.
  - For example, reading/writing disk, sending network packet, waiting for keystroke, updating display.
  - While waiting for results, the process often cannot do anything, so it **blocks**, and the OS schedules a different process to run.

Multiprogramming processes

The three basic process states:



- When one process is Blocked, OS can schedule a different process that is Ready
- Even with a single processor, the OS can provide the illusion of many processes running simultaneously
- OS usually sets a maximum runtime before switching limit for processes (timeslice)

Key difference between kernel and processes: privilege

- Processes have limited access to the computer
  - Hardware supports different "modes" of execution (kernel and user)
  - Kernel mode has access to physical memory and special instructions

- They run when the OS lets them
- They have access to the memory the OS gives them

- They cannot access many things directly
  - Must ask the OS to do so for them

Break + Question

- Is it safe for two processes to have the same code section?

Break + Question

- Is it safe for two processes to have the same code section?

Usually yes!

- The OS can mark the code section as read-only

- Example: multiple instances of a shell share the same code

- Self-modifying code would be a problem…

Outline

- Processes
- **System Calls**
- Process Creation
- Signals
- Threads

Things a program cannot do itself

- Print “hello world”
  - *because the display is a shared resource.*
- Download a web page
  - *because the network card is a shared resource.*
- Save or read a file
  - *because the filesystem is a shared resource, and the OS wants to check file permissions first.*
- Launch another program
  - *because processes are managed by the OS*
- Send data to another program
  - *because each program runs in isolation, one at a time*

How does a process ask the OS to do something?

- Certain things can only be accessed from kernel mode
  - All of memory, I/O devices, etc.

- **Bad Idea** to allow processes to switch into kernel mode
  - We do NOT trust processes
  - So there shouldn't be any instruction that switches to kernel mode…

- Requirements
  1. Switch execution to the kernel
  2. Change into kernel mode
  3. Inform the kernel what you want it to do

Hardware can save us!

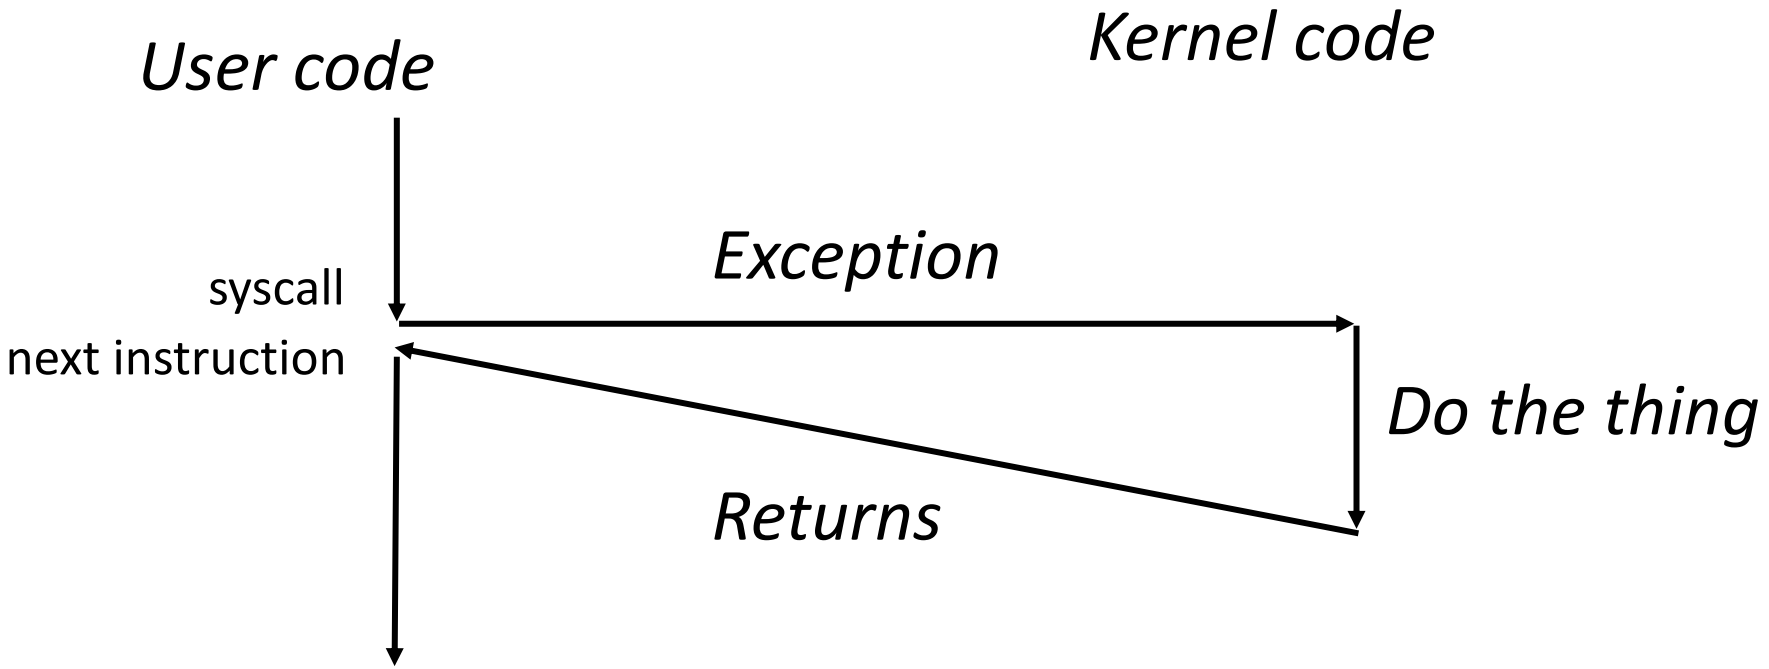
- Solution: hardware instruction – trap
  - Also known as exception or fault

- When instruction runs:
  1. Mode is changed to kernel mode
     AND
  2. Instruction Pointer is moved to a known location in the kernel

- Same mechanism is used for other exceptions
  - Division by zero, invalid memory access
  - Also very similar to hardware interrupts

System call example

- System call: making a request of the OS from a process
  - Uses exceptional control flow to enter OS kernel
  - Returns back to process when complete
    - Instruction *after* the system call



System call steps (simplification)

1. Process loads parameters into registers (just like a function call)
2. Process executes trap instruction (`int`, `syscall`, `svc`, etc.)
3. Hardware moves instruction pointer to "handler" and switches to kernel mode
4. OS checks what the process wants to do from registers
5. OS decides *whether* the process is allowed to do so
6. OS sets process state to blocked

Returning from a system call (simplification)

- After OS finishes whatever operation it was asked to do
  - And when the process is scheduled to run again

1. OS places return result in a register (just like a function call)
2. OS sets process state to running
3. OS changes mode to user mode (and sets virtual memory stuff)
4. OS sets instruction pointer to instruction *after* the system call

- Process continues and can use results of system call

System calls trigger *context switches*

- Context switch: the action of storing the state of a process so it can be resumed later and entering into the kernel

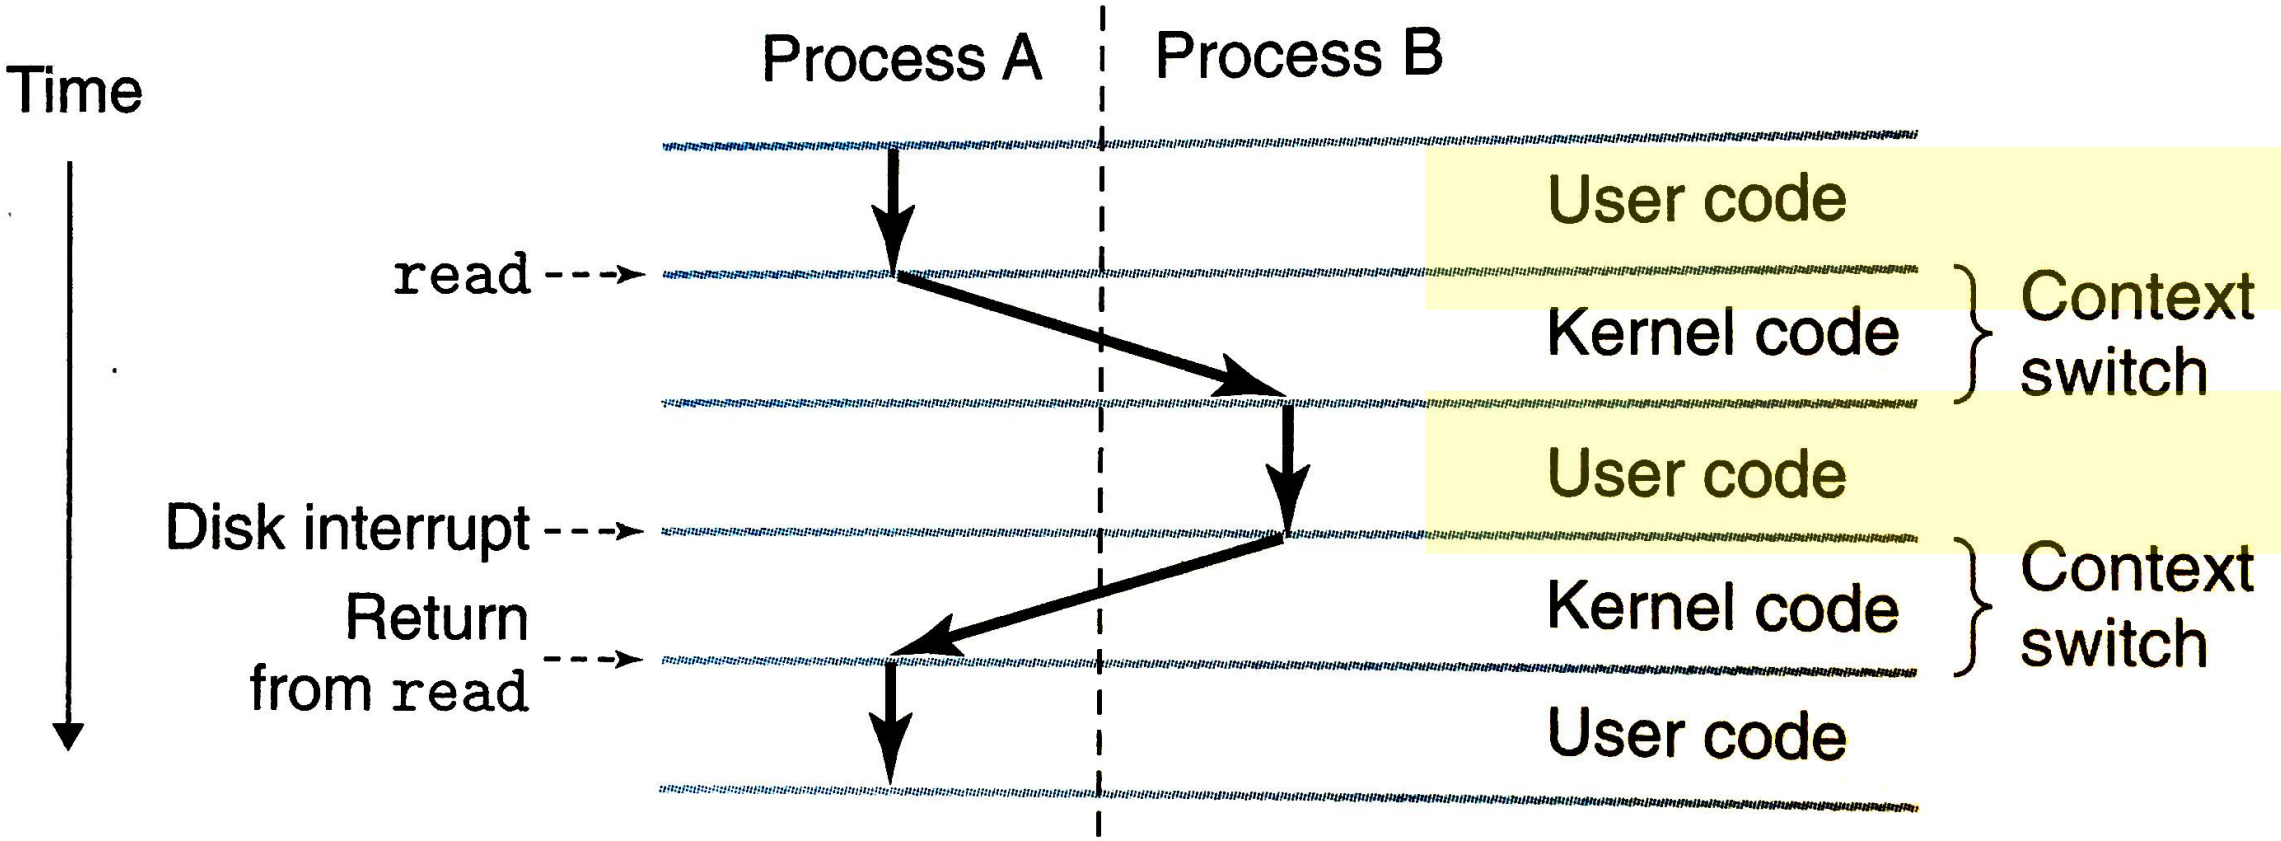


Diagram from Bryant & O'Hallaron book

Linux system calls

- Example system calls
  - https://man7.org/linux/man-pages/man2/syscalls.2.html

Number	***Name***	***Description***
0	`read`	Read file
1	`write`	Write file
2	`open`	Open file
3	`close`	Close file
4	`stat`	Get info about file
57	`fork`	Create process
59	`execve`	Execute a program
60	`_exit`	Terminate process
62	`kill`	Send signal to process

Many other system calls

- POSIX contains many others, for example `time()`
  - And especially lots of old ones

- Windows or other operating systems will have entirely different system calls
  - Same basic idea for how they function though

Outline

- Processes
- System Calls
- **Process Creation**
- Signals
- Threads

Example system call usage

- Create new processes with system calls

- From process view:
  - Just look like regular C functions
  - Take arguments, return values

- Underneath:
  - Function uses special assembly instruction to trigger exception

Process system calls

`pid_t fork(void);`

- Create a new process that is a copy of the current one
- Returns either PID of child process (parent) or 0 (child)

`void _exit(int status);`

- Exit the current process (exit(), the library call cleans things up first)

`pid_t waitpid(pid_t pid, int *status, int options);`

- Suspends the current process until a child (*pid*) terminates

`int execve(const char *filename, char *const argv[], char *const envp[]);`

- Execute a new program, replacing the existing one

Creating a new process

```
#include <stdio.h>
#include <unistd.h>

int main(){
  if(fork() == 0) {
    printf("Child!\n");
  } else {
    printf("Parent!\n");
  }

  printf("Both!\n");
  return 0;
}
```

Creating a new process

```
#include <stdio.h>
#include <unistd.h>

int main(){
  if(fork() == 0) {
    printf("Child!\n");
  } else {
    printf("Parent!\n");
  }

  printf("Both!\n");
  return 0;
}
```

Existential crisis

Executing a new program

```
#include <stdio.h>
#include <unistd.h>

int main(){
  if(fork() == 0) {
    execve("/bin/python3", ...);
  } else {
    printf("Parent!\n");
  }

  printf("Only parent!\n");
  return 0;
}
```

Creating your own shell

https://danishpraka.sh/2018/01/15/write-a-shell.html

```
void execute(char** args) {
  if (strcmp(args[0], "exit") == 0) {
    exit(); // exit the shell when requested
  }

  pid_t cpid = fork();
  if (cpid == 0) {
    if (execvp(args[0], args) < 0) { // child, execute new process
      printf("command not found: %s\n", args[0]);
    }
  } else {
    waitpid(cpid, & status, WUNTRACED); // parent, wait for process to be complete
}}

int main(){
  char** args;
  while(1){
    printf("> ");
    args = parse_incoming_text(); // complicated in C unfortunately
    execute(args);
}}
```

Creating your own shell

https://danishpraka.sh/2018/01/15/write-a-shell.html

```
void execute(char** args) {
  if (strcmp(args[0], "exit") == 0) {
    exit(); // exit the shell when requested
  }

  pid_t cpid = fork();
  if (cpid == 0) {
    if (execvp(args[0], args) < 0) { // child, execute new process
      printf("command not found: %s\n", args[0]);
    }
  } else {
    waitpid(cpid, & status, WUNTRACED); // parent, wait for process to be complete
}}

int main(){
  char** args;
  while(1){
    printf("> ");
    args = parse_incoming_text(); // complicated in C unfortunately
    execute(args);
}}
```

Break + Question

- What does the following code do?

```
#include <stdio.h>
#include <sys/types.h>

int main() {
  while(1){
    fork();
  }
  return 0;
}
```

Break + Question

- What does the following code do?

```
#include <stdio.h>
#include <sys/types.h>

int main() {
  while(1){
    fork();
  }
  return 0;
}
```

- Creates a new process
  - Then each process creates a new process
  - Then each of those creates a new process…
- Known as a Fork bomb!
  - Machine eventually runs out of memory and processing power and will stop working
- Defense: limit number of processes per user

Fork bombs in various languages

- Python fork bomb

```
import os
while 1:
   os.fork()
```

- Rust fork bomb

```
#[allow(unconditional_recursion)]
fn main() {
    std::thread::spawn(main);
    main();
}
```

- Bash fork bomb

```
:(){ :|:& };:
```

- Bash with spacing and a clearer function name

```
fork() {
    fork | fork &
}
fork
```

Outline

- Processes
- System Calls
- Process Creation
- **Signals**
- Threads

Alerting processes of events

- How do we let a process know there was an event?
  - Errors
  - Termination
  - User commands (like CTRL-C or CTRL-\)

- Events could happen whenever
  - Need to interrupt process control flow and run an event handler
  - Linux mechanism to do so is called “signals”

Signals are asynchronous messages to processes

- Sometimes the OS wants to send something like an interrupt to a process
  - Your child process completed
  - You tried to use an illegal instruction
  - You accessed invalid memory
  - You are terminating now

- In POSIX systems, this idea is called “Signals”

```
 1) SIGHUP     2) SIGINT   3) SIGQUIT   4) SIGILL  5) SIGTRAP
 6) SIGABRT    7) SIGBUS   8) SIGFPE    9) SIGKILL 10) SIGUSR1
11) SIGSEGV   12) SIGUSR2 13) SIGPIPE  14) SIGALRM 15) SIGTERM
16) SIGSTKFLT 17) SIGCHLD 18) SIGCONT  19) SIGSTOP 20) SIGTSTP
21) SIGTTIN   22) SIGTTOU 23) SIGURG   24) SIGXCPU 25) SIGXFSZ
26) SIGVTALRM 27) SIGPROF 28) SIGWINCH 29) SIGIO   30) SIGPWR
31) SIGSYS           ...
```

Signals are asynchronous messages to processes

- Sometimes the OS wants to send something like an interrupt to a process
  - Your child process completed
  - You tried to use an illegal instruction
  - You accessed invalid memory
  - You are terminating now

- In POSIX systems, this idea is called “Signals”

```
 1) SIGHUP     2) SIGINT     3) SIGQUIT    4) SIGILL     5) SIGTRAP
 6) SIGABRT    7) SIGBUS     8) SIGFPE     9) SIGKILL   10) SIGUSR1
11) SIGSEGV   12) SIGUSR2   13) SIGPIPE   14) SIGALRM   15) SIGTERM
16) SIGSTKFLT 17) SIGCHLD   18) SIGCONT   19) SIGSTOP   20) SIGTSTP
21) SIGTTIN   22) SIGTTOU   23) SIGURG    24) SIGXCPU   25) SIGXFSZ
26) SIGVTALRM 27) SIGPROF   28) SIGWINCH  29) SIGIO     30) SIGPWR
31) SIGSYS           ...
```

Process Errors

Signals are asynchronous messages to processes

- Sometimes the OS wants to send something like an interrupt to a process
  - Your child process completed
  - You tried to use an illegal instruction
  - You accessed invalid memory
  - You are terminating now

- In POSIX systems, this idea is called "Signals"

```
 1) SIGHUP     2) SIGINT    3) SIGQUIT    4) SIGILL    5) SIGTRAP
 6) SIGABRT    7) SIGBUS    8) SIGFPE     9) SIGKILL  10) SIGUSR1
11) SIGSEGV   12) SIGUSR2  13) SIGPIPE   14) SIGALRM  15) SIGTERM
16) SIGSTKFLT 17) SIGCHLD  18) SIGCONT   19) SIGSTOP  20) SIGTSTP
21) SIGTTIN   22) SIGTTOU  23) SIGURG    24) SIGXCPU  25) SIGXFSZ
26) SIGVTALRM 27) SIGPROF  28) SIGWINCH  29) SIGIO    30) SIGPWR
31) SIGSYS           ...
```

Process Termination

Sending signals

- OS sends signals when it needs to

- Processes can ask the OS send signals with a system call
  - `int kill(pid_t pid, int sig);`

- Users send signals through OS from command line or keyboard
  - Shell command: kill -9 *pid* (SIGKILL)
  - CTRL-C (SIGINT)

Handling signals

- Programs can register a function to handle individual signals
  - `signal(int sig, sighandler_t handler);`
- OS keeps track of signal handlers for each signal
  - Calls that function when a signal occurs
- What is the process supposed to do about it?
  - Do some *quick* processing to handle it
  - Reset the process and try again
  - Quit the process (default handler)

Example: catching a signal

```
#include <stdbool.h>
#include <stdlib.h>
#include <stdio.h>

#include <unistd.h>
#include <signal.h>
```

```
void sighandler (int signum) {
   printf("HA HA You can't kill me!\n");
}
int main (void) {
   signal(SIGINT, sighandler);
   printf("Starting\n");
   while(true) {
      printf("Going to sleep for a second...\n");
      sleep(1);
   }
   return 0;
}
```

- Signals and Firefox

Outline

- Processes
- System Calls
- Process Creation
- Signals
- **Threads**

Software Tasks: Threads

Unit of execution *within* a process

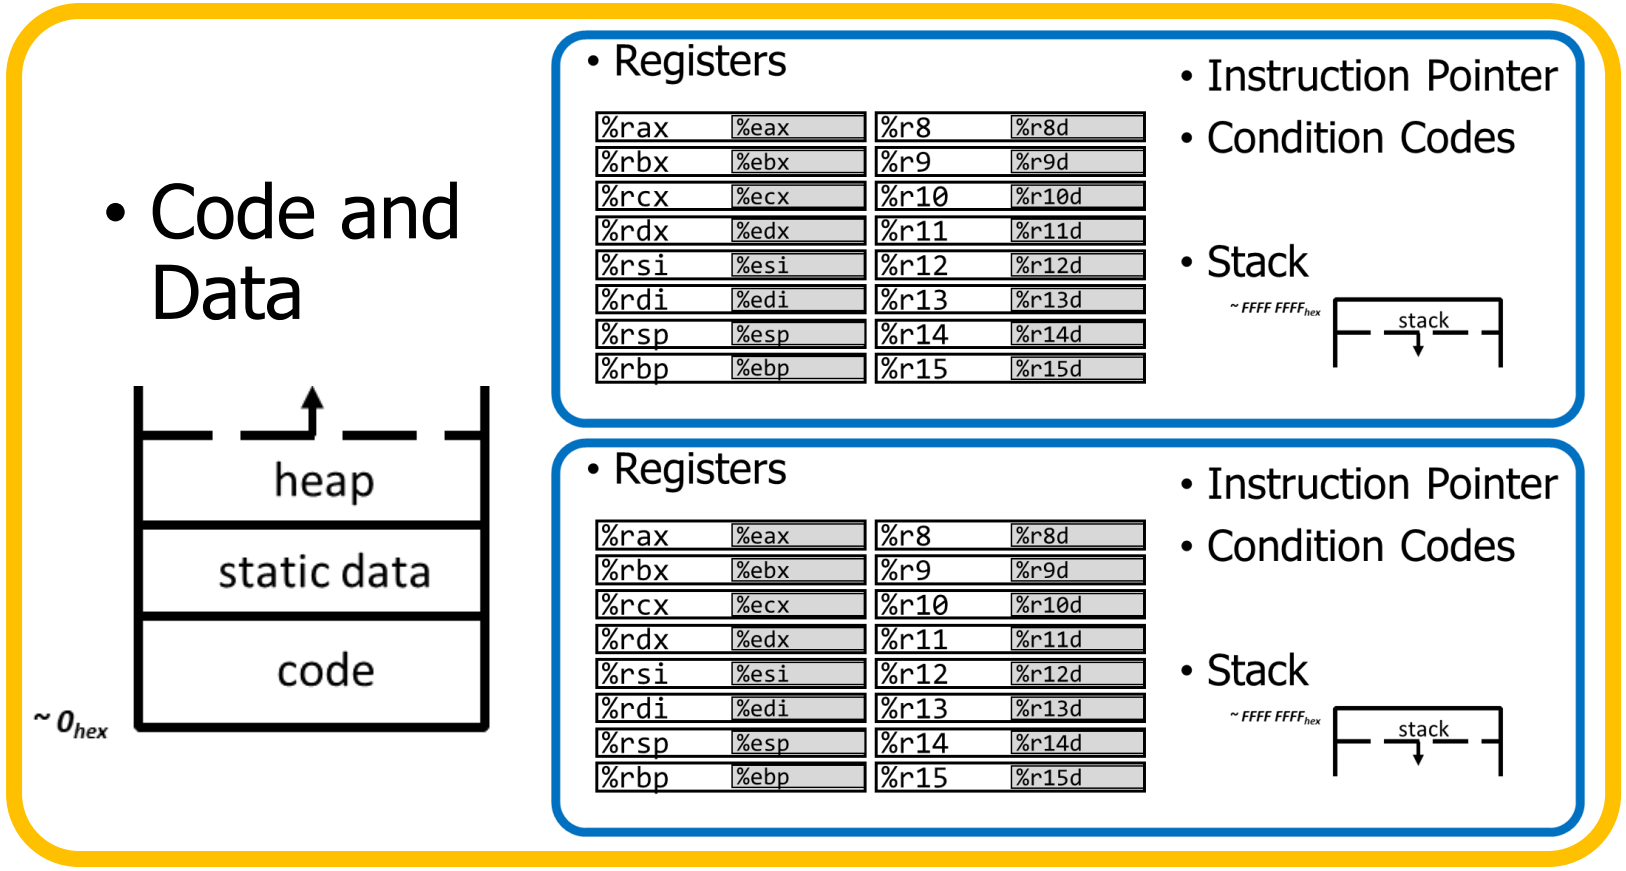
Processes discussed so far have a single thread

- They "have a single thread of execution"
- They "are single-threaded"

But a single process could have multiple threads

Alternate view of a process

- A process could have multiple threads
  - Each with its own registers and stack



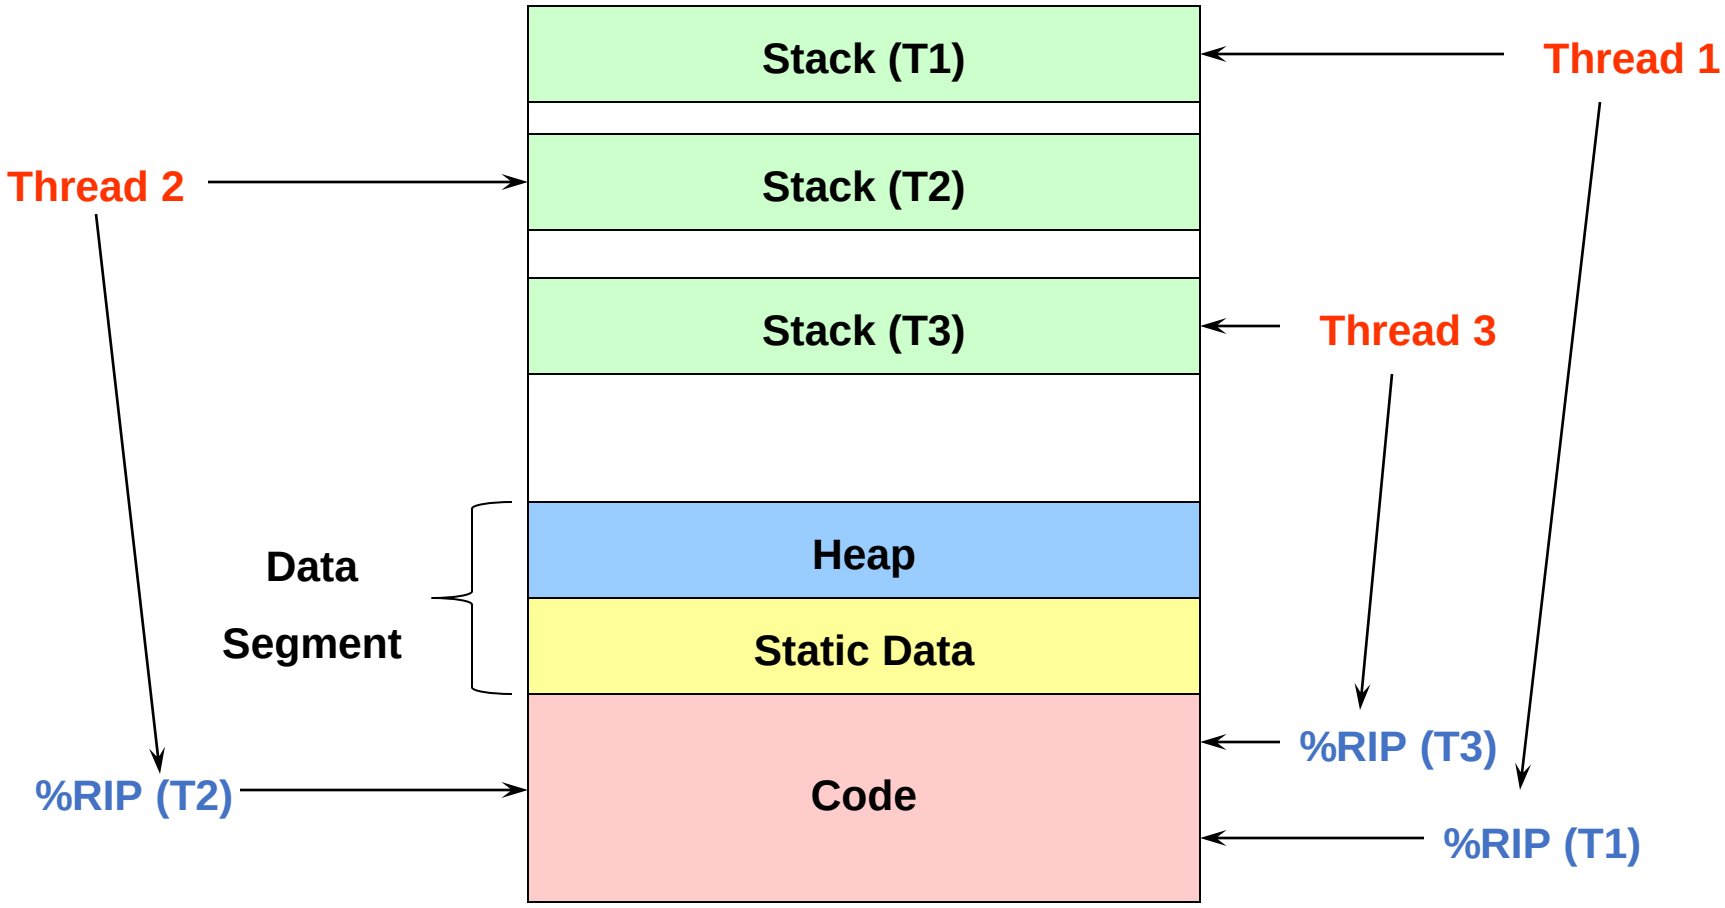
Threads have separate:

- Instruction Pointer
- Registers
- Stack Memory
- Condition Codes

Threads share:

- Code
- Global variables

Process address space with threads



Thread use case: web browser

Let’s say you’re implementing a web browser:

You want a tab for each web page you open:

- The same code loads each website (shared code section)
- The same global settings are shared by each tab (shared data section)
- Each tab does have separate state (separate stack and registers)

Disclaimer: Actually, modern browsers use separate processes for each tab for a variety of reasons including performance and security. But they used to use threads.

Thread use case: user interfaces

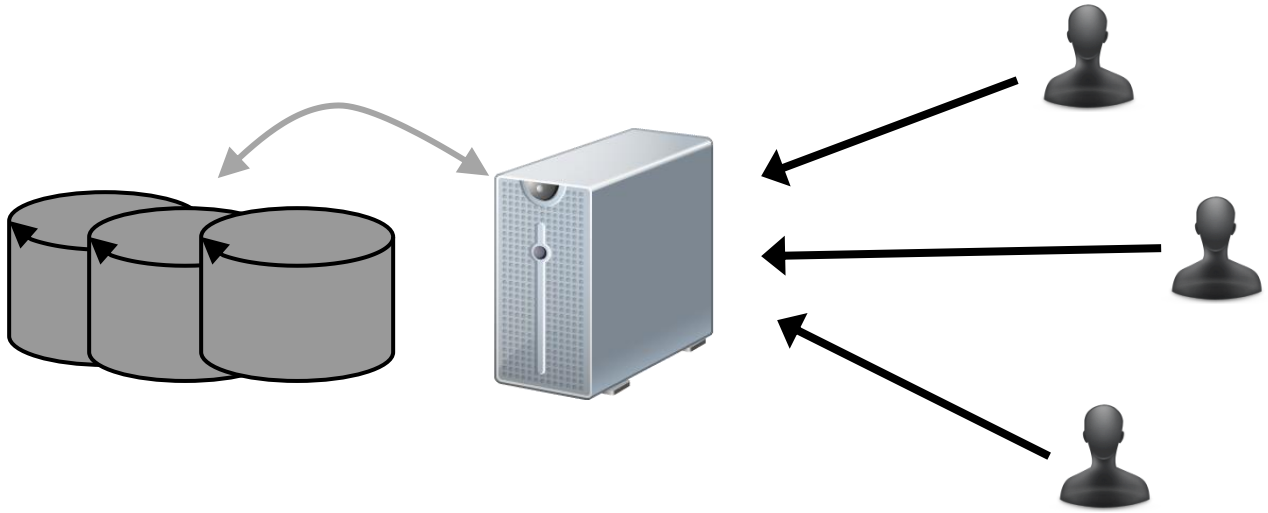
- Even if there is only a single processor core, threads are useful

- Single-threaded User Interface
  - While processing actions, the UI is frozen

```
main() {
   while(true) {
         check_for_UI_interactions();
         process_UI_actions(); // UI freezes while processing
   }
}
```

Thread use case: web server

- Example: Web server
  - Receives multiple simultaneous requests
  - Reads web pages from disk to satisfy each request



Web server option 1: handle one request at a time

Request 1 arrives
Server reads in request 1
Server starts disk I/O for request 1
Request 2 arrives
Disk I/O for request 1 finishes
Server responds to request 1
Server reads in request 2

- Easy to program, but slow
  - Can’t overlap disk requests with computation
  - Can’t overlap either with network sends and receives

Web server option 1: event-driven model

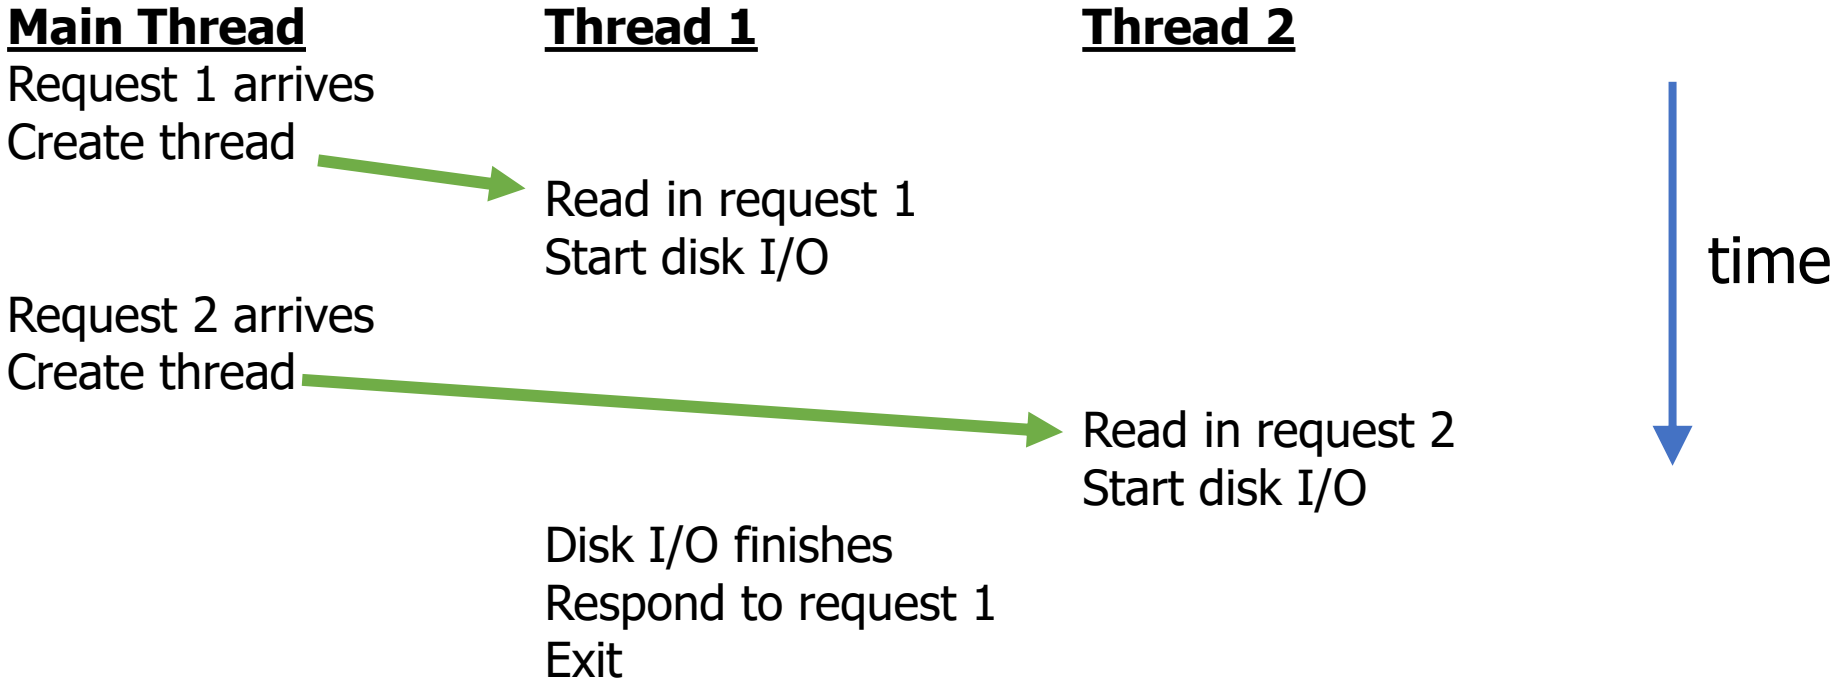
- Issue I/Os, but don't wait for them to complete

  Request 1 arrives
  Server reads in request 1
  Server starts disk I/O for request 1
  Request 2 arrives
  Server reads in request 2
  Server starts disk I/O for request 2
  Disk I/O for request 1 completes
  Server responds to request 1

- Fast, but hard to program
  - Must remember which requests are in flight and which I/O goes where
  - Lots of extra state

Web server option 3: multi-threaded web server

- One thread per request. Thread handles only that request.



- Easy to program (maybe), and fast!
  - State is stored in the stacks of each thread and the thread scheduler
  - Simple to program if they are independent…

More Practical Motivation

Back to Jeff Dean's "Numbers Everyone Should Know"

L1 cache reference	0.5 ns
Branch mispredict	5 ns
L2 cache reference	7 ns
Mutex lock/unlock	25 ns
Main memory reference	100 ns
Compress 1K bytes with Zippy	3,000 ns
Send 2K bytes over 1 Gbps network	20,000 ns
Read 1 MB sequentially from memory	250,000 ns
Round trip within same datacenter	500,000 ns
Disk seek	10,000,000 ns
Read 1 MB sequentially from disk	20,000,000 ns
Send packet CA->Netherlands->CA	150,000,000 ns

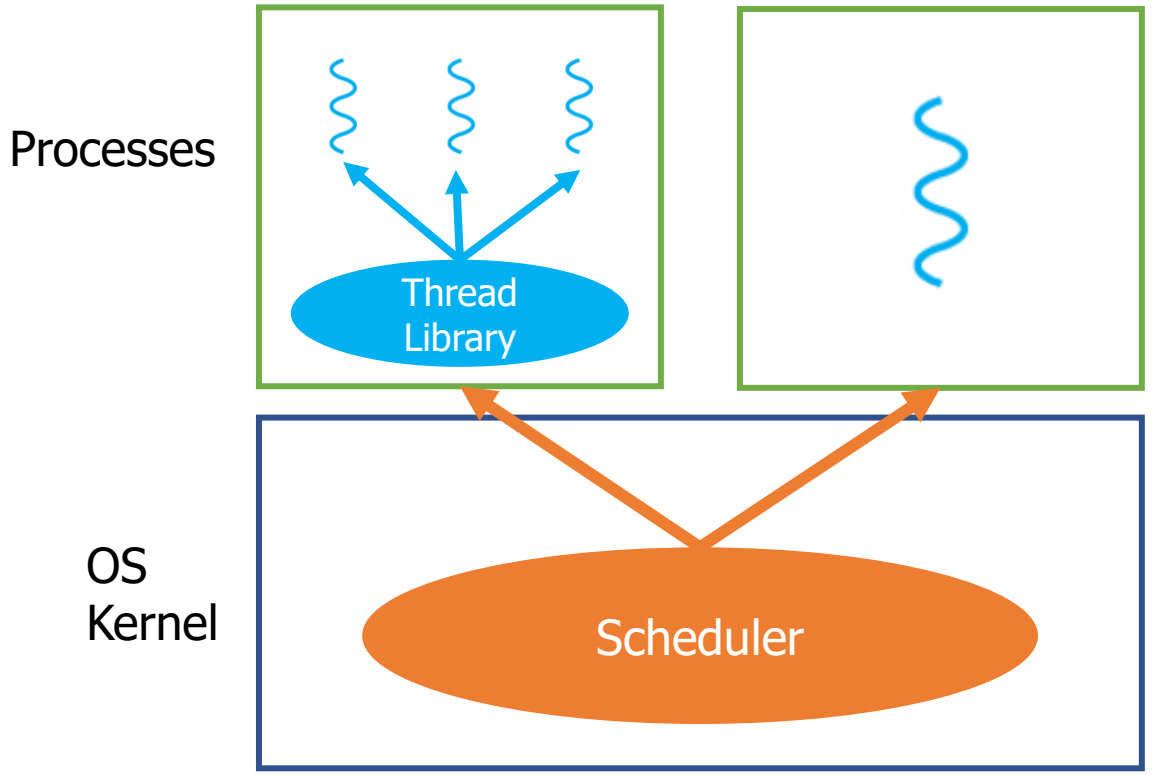
Handle I/O in separate thread, avoid blocking other progress

Models for thread libraries: **User Threads**

- Thread scheduling is implemented within the process
  - OS only knows about the process, not the threads

- Upsides
  - Works on any hardware or OS
  - Performance is better when creating and switching

- Downsides
  - A system call in any thread **blocks all threads**



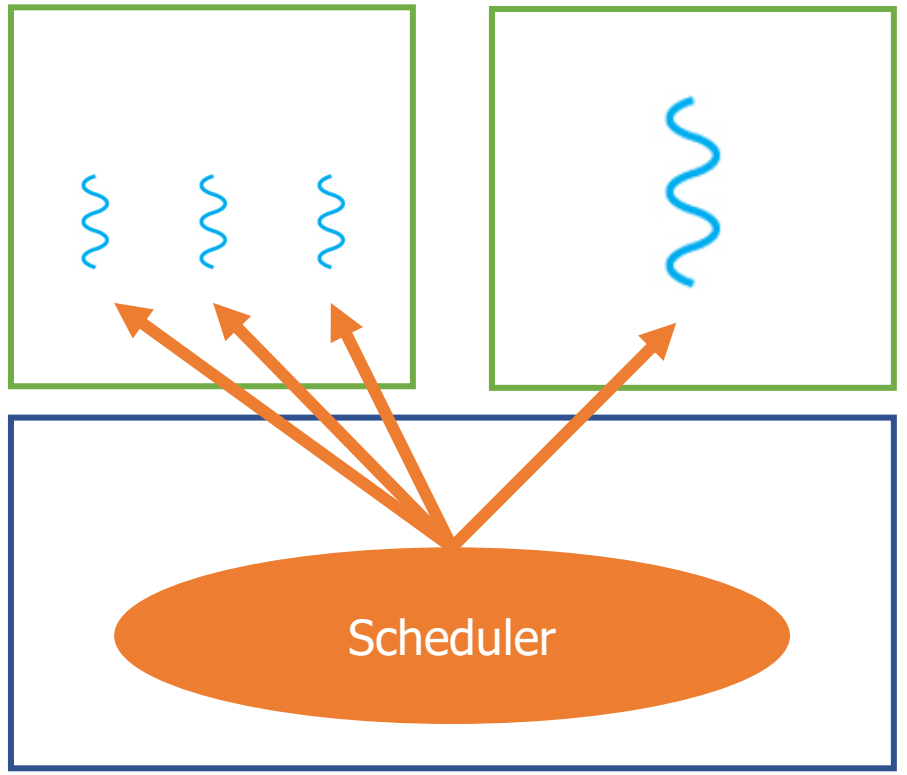
Models for thread libraries: **Kernel Threads**

- Thread scheduling is implemented by the operating system
  - OS manages the threads within each process

- Upsides
  - Other threads can continue while one blocks on I/O
  - No additional scheduler

- Downsides
  - Higher overhead

- This is what we'll focus on in CS343



Threads versus Processes

Threads

- **`pthread_create()`**
  - Creates a thread
  - ***Shares*** all memory with all threads of the process.
  - Scheduled independently of parent
- **`pthread_join()`**
  - Waits for a particular thread to finish
- Can communicate by reading/writing (shared) global variables.

Processes

- **`fork()`**
  - Creates a single-threaded process
  - ***Copies*** all memory from parent
    - Can be quick using copy-on-write
  - Scheduled independently of parent
- **`waitpid()`**
  - Waits for a particular child process to finish
- Can communicate by setting up shared memory, pipes, reading/writing files, or using sockets (network).

POSIX Threads Library: pthreads

- https://man7.org/linux/man-pages/man7/pthreads.7.html

```
int pthread_create(pthread_t *thread, const pthread_attr_t *attr,
void *(*start_routine)(void*), void *arg);
```

- thread is created executing *start_routine* with *arg* as its sole argument.
- return is implicit call to pthread_exit

```
void pthread_exit(void *value_ptr);
```

- terminates the thread and makes *value_ptr* available to any successful join

```
int pthread_join(pthread_t thread, void **value_ptr);
```

- suspends execution of the calling thread until the target *thread* terminates.
- On return with a non-NULL *value_ptr* the value passed to *pthread_exit()* by the terminating thread is made available in the location referenced by *value_ptr*.

Pthread system call example

- What happens when pthread_create() is called in a process?

```
Library:
    int pthread_create(…) {
        Do some work like a normal function
        Put syscall number into register
        Put args into registers
        Special trap instruction
```

`clone` (56) syscall on Linux

```
Kernel:
    Get args from regs
    Do the work to spawn the new thread
    Store return value in %eax
```

```
        Get return values from regs
        Do some more work like a normal function
    };
```

Outline

- Processes
- System Calls
- Process Creation
- Signals
- Threads

Bonus Materials

Threads Example

```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <string.h>

int common = 162;

void *threadfun(void *threadid)
{
  long tid = (long)threadid;
  printf("Thread #%lx stack: %lx common: %lx (%d)\n", tid,
         (unsigned long) &tid, (unsigned long) &common, common++);
  pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
  long t;
  int nthreads = 2;
  if (argc > 1) {
    nthreads = atoi(argv[1]);
  }
  pthread_t *threads = malloc(nthreads*sizeof(pthread_t));
  printf("Main stack: %lx, common: %lx (%d)\n",
         (unsigned long) &t,(unsigned long) &common, common);
  for(t=0; t<nthreads; t++){
    int rc = pthread_create(&threads[t], NULL, threadfun, (void *)t);
    if (rc){
      printf("ERROR; return code from pthread_create() is %d\n", rc);
      exit(-1);
    }
  }

  for(t=0; t<nthreads; t++){
    pthread_join(threads[t], NULL);
  }
  pthread_exit(NULL);           /* last thing in the main thread  */
}
```

Threads Example

- Reads N from process arguments
- Creates N threads
- Each one prints a number, then increments it, then exits
- Main process waits for all of the threads to finish

```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <string.h>

int common = 162;

void *threadfun(void *threadid)
{
  long tid = (long)threadid;
  printf("Thread #%lx stack: %lx common: %lx (%d)\n", tid,
         (unsigned long) &tid, (unsigned long) &common, common++);
  pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
  long t;
  int nthreads = 2;
  if (argc > 1) {
    nthreads = atoi(argv[1]);
  }
  pthread_t *threads = malloc(nthreads*sizeof(pthread_t));
  printf("Main stack: %lx, common: %lx (%d)\n",
         (unsigned long) &t,(unsigned long) &common, common);
  for(t=0; t<nthreads; t++){
    int rc = pthread_create(&threads[t], NULL, threadfun, (void *)t);
    if (rc){
      printf("ERROR; return code from pthread_create() is %d\n", rc);
      exit(-1);
    }
  }

  for(t=0; t<nthreads; t++){
    pthread_join(threads[t], NULL);
  }
  pthread_exit(NULL);           /* last thing in the main thread  */
}
```

Threads Example

```
(base) CullerMac19:code04 culler$ ./pthread 4
Main stack: 7ffee2c6b6b8, common: 10cf95048 (162)
Thread #1 stack: 70000d83bef8 common: 10cf95048 (162)
Thread #3 stack: 70000d941ef8 common: 10cf95048 (164)
Thread #2 stack: 70000d8beef8 common: 10cf95048 (165)
Thread #0 stack: 70000d7b8ef8 common: 10cf95048 (163)
```

```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <string.h>

int common = 162;

void *threadfun(void *threadid)
{
  long tid = (long)threadid;
  printf("Thread #%lx stack: %lx common: %lx (%d)\n", tid,
         (unsigned long) &tid, (unsigned long) &common, common++);
  pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
  long t;
  int nthreads = 2;
  if (argc > 1) {
    nthreads = atoi(argv[1]);
  }
  pthread_t *threads = malloc(nthreads*sizeof(pthread_t));
  printf("Main stack: %lx, common: %lx (%d)\n",
         (unsigned long) &t,(unsigned long) &common, common);
  for(t=0; t<nthreads; t++){
    int rc = pthread_create(&threads[t], NULL, threadfun, (void *)t);
    if (rc){
      printf("ERROR; return code from pthread_create() is %d\n", rc);
      exit(-1);
    }
  }

  for(t=0; t<nthreads; t++){
    pthread_join(threads[t], NULL);
  }
  pthread_exit(NULL);           /* last thing in the main thread  */
}
```

Check your understanding

```
(base) CullerMac19:code04 culler$ ./pthread 4
Main stack: 7ffee2c6b6b8, common: 10cf95048 (162)
Thread #1 stack: 70000d83bef8 common: 10cf95048 (162)
Thread #3 stack: 70000d941ef8 common: 10cf95048 (164)
Thread #2 stack: 70000d8beef8 common: 10cf95048 (165)
Thread #0 stack: 70000d7b8ef8 common: 10cf95048 (163)
```

1. How many threads are in this program?
2. Does the main thread join with the threads in the same order that they were created?
3. Do the threads exit in the same order they were created?
4. If we run the program again, would the result change?

```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <string.h>

int common = 162;

void *threadfun(void *threadid)
{
  long tid = (long)threadid;
  printf("Thread #%lx stack: %lx common: %lx (%d)\n", tid,
         (unsigned long) &tid, (unsigned long) &common, common++);
  pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
  long t;
  int nthreads = 2;
  if (argc > 1) {
    nthreads = atoi(argv[1]);
  }
  pthread_t *threads = malloc(nthreads*sizeof(pthread_t));
  printf("Main stack: %lx, common: %lx (%d)\n",
         (unsigned long) &t,(unsigned long) &common, common);
  for(t=0; t<nthreads; t++){
    int rc = pthread_create(&threads[t], NULL, threadfun, (void *)t);
    if (rc){
      printf("ERROR; return code from pthread_create() is %d\n", rc);
      exit(-1);
    }
  }

  for(t=0; t<nthreads; t++){
    pthread_join(threads[t], NULL);
  }
  pthread_exit(NULL);           /* last thing in the main thread  */
}
```

Check your understanding

```
(base) CullerMac19:code04 culler$ ./pthread 4
Main stack: 7ffee2c6b6b8, common: 10cf95048 (162)
Thread #1 stack: 70000d83bef8 common: 10cf95048 (162)
Thread #3 stack: 70000d941ef8 common: 10cf95048 (164)
Thread #2 stack: 70000d8beef8 common: 10cf95048 (165)
Thread #0 stack: 70000d7b8ef8 common: 10cf95048 (163)
```

1. How many threads are in this program? **Five**
2. Does the main thread join with the threads in the same order that they were created? **Yes**
3. Do the threads exit in the same order they were created? **Maybe??**
4. If we run the program again, would the result change? **Possibly!**

```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <string.h>

int common = 162;

void *threadfun(void *threadid)
{
  long tid = (long)threadid;
  printf("Thread #%lx stack: %lx common: %lx (%d)\n", tid,
         (unsigned long) &tid, (unsigned long) &common, common++);
  pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
  long t;
  int nthreads = 2;
  if (argc > 1) {
    nthreads = atoi(argv[1]);
  }
  pthread_t *threads = malloc(nthreads*sizeof(pthread_t));
  printf("Main stack: %lx, common: %lx (%d)\n",
         (unsigned long) &t,(unsigned long) &common, common);
  for(t=0; t<nthreads; t++){
    int rc = pthread_create(&threads[t], NULL, threadfun, (void *)t);
    if (rc){
      printf("ERROR; return code from pthread_create() is %d\n", rc);
      exit(-1);
    }
  }

  for(t=0; t<nthreads; t++){
    pthread_join(threads[t], NULL);
  }
  pthread_exit(NULL);           /* last thing in the main thread  */
}
```
