Lecture 05: Advanced Concurrency Control

CS343 – Operating Systems

Branden Ghena – Spring 2022

Some slides borrowed from:
Stephen Tarzia (Northwestern), and Shivaram Venkataraman (Wisconsin)

Today's Goals

- Understand how we can apply locks to gain correctness and maintain performance
  - Counter
  - Data Structures

- Signaling between threads to enforce ordering
  - Condition Variables
  - Semaphores

Review: Locks/Mutexes

- Simple mutual exclusion primitive
- Init(), Acquire(), Release()
- Implementations trade complexity, fairness, and performance
  - Spinlocks
  - Ticket locks
  - Yielding locks
  - Queueing locks

Outline

- **Applying Locks**
- Concurrent Data Structures
- Ordering with Condition Variables
- Semaphores

Review: Need to enforce mutual exclusion on critical sections

```c
#include <stdio.h>
#include <pthread.h>

static volatile int counter = 0;
static const int LOOPS = 1e9;

void* mythread(void* arg) {
  printf("%s: begin\n", (char*)arg);
  for (int i=0; i<LOOPS; i++) {
    counter++;
  }
  printf("%s: done\n", (char*)arg);
  return NULL;
}
```

```c
int main(int argc, char* argv[]) {
  pthread_t p1, p2;
  printf("main: begin (counter = %d)\n", counter);
  pthread_create(&p1, NULL, mythread, "A");
  pthread_create(&p2, NULL, mythread, "B");

  // wait for threads to finish
  pthread_join(p1, NULL);
  pthread_join(p2, NULL);
  printf("main: done with both (counter = %d, goal
was %d)\n", counter, 2*LOOPS);
  return 0;
}
```

Naively locked counter example

```c
#include <stdio.h>
#include <pthread.h>

static volatile int counter = 0;
static const int LOOPS = 1e9;
static pthread_mutex_t lock;

void* mythread(void* arg) {
  printf("%s: begin\n", (char*)arg);
  for (int i=0; i<LOOPS; i++) {
    pthread_mutex_lock(&lock);
    counter++;
    pthread_mutex_unlock(&lock);
  }
  printf("%s: done\n", (char*)arg);
  return NULL;
}
```

```c
int main(int argc, char* argv[]) {
  pthread_t p1, p2;
  pthread_mutex_init(&lock, 0);
  printf("main: begin (counter = %d)\n", counter);
  pthread_create(&p1, NULL, mythread, "A");
  pthread_create(&p2, NULL, mythread, "B");

  // wait for threads to finish
  pthread_join(p1, NULL);
  pthread_join(p2, NULL);
  printf("main: done with both (counter = %d, goal
was %d)\n", counter, 2*LOOPS);
  return 0;
}
```

Problem: locking overhead decreases performance

When iterating one billion times:

Single-threaded counter:	3.850 seconds
Multithreaded no-lock counter:	4.700 seconds (Broken!)
Naïve-locked counter:	80.000 seconds (Correct…)

- Formerly loop contained 3 instructions (mov, add, mov)
- Now it has
  - Two function calls
  - Multiple instructions inside of those
  - Possibly even interaction with the OS…
  - 3 instructions -> 60 instructions

Simple mutual exclusion: one big lock

- Simple solution “one big lock”
  - Find all the function calls that interact with shared memory
  - Lock at the start of each function call and unlock at the end

- Essentially, no concurrent access
  - Correct but poor performance
  - If you’ve forgotten all of this years from now, “one big lock” will still work

Counter example with big lock technique

```c
#include <stdio.h>
#include <pthread.h>

static volatile int counter = 0;
static const int LOOPS = 1e9;
static pthread_mutex_t lock;

void* mythread(void* arg) {
  pthread_mutex_lock(&lock);
  printf("%s: begin\n", (char*)arg);
  for (int i=0; i<LOOPS; i++) {
    counter++;
  }
  printf("%s: done\n", (char*)arg);
  pthread_mutex_unlock(&lock);
  return NULL;
}
```

```c
int main(int argc, char* argv[]) {
  pthread_t p1, p2;
  pthread_mutex_init(&lock, 0);
  printf("main: begin (counter = %d)\n", counter);
  pthread_create(&p1, NULL, mythread, "A");
  pthread_create(&p2, NULL, mythread, "B");

  // wait for threads to finish
  pthread_join(p1, NULL);
  pthread_join(p2, NULL);
  printf("main: done with both (counter = %d, goal
was %d)\n", counter, 2*LOOPS);
  return 0;
}
```

Problem: locking decreases performance

Single-threaded counter:	3.850 seconds
Multithreaded no-lock counter:	4.700 seconds (Broken!)
Naïve-locked counter:	80.000 seconds
Big lock counter:	3.895 seconds

- Big lock technique basically returned us to single-threaded execution time (and single-threaded implementation)
- Why is the no-lock multithreaded version so slow?
  - Not 100% certain
  - Likely something to do with hardware memory/cache consistency

Reducing lock overhead

- We want to enable parallelism, but deal with less lock overhead
  - Need to increase the amount of work done when not locked
  - Goal: lots of parallel work per lock/unlock event

- "Sloppy" updates to global state
  - Keep local state that is operated on
  - Occasionally synchronize global state with current local state

- Counter example
  - Keep a local counter for each thread (not shared memory)
  - Add local counter to global counter periodically

Sloppy counter example

```c
#include <stdio.h>
#include <pthread.h>

static volatile int counter = 0;
static const int LOOPS = 1e9;
static pthread_mutex_t lock;

void* mythread(void* arg) {
  int sloppy_count = 0;
  printf("%s: begin\n", (char*)arg);
  for (int i=0; i<LOOPS; i++) {
    sloppy_count++;
    if (i%1000 == 0) {
        pthread_mutex_lock(&lock);
        counter += sloppy_count;
        pthread_mutex_unlock(&lock);
        sloppy_count = 0;
    }
  }
```

```c
int main(int argc, char* argv[]) {
  pthread_t p1, p2;
  pthread_mutex_init(&lock, 0);
  printf("main: begin (counter = %d)\n", counter);
  pthread_create(&p1, NULL, mythread, "A");
  pthread_create(&p2, NULL, mythread, "B");

  // wait for threads to finish
  pthread_join(p1, NULL);
  pthread_join(p2, NULL);
  printf("main: done with both (counter = %d, goal
was %d)\n", counter, 2*LOOPS);
  return 0;
}
```

Offscreen Tail condition: don't forget to update "counter" again when the for loop is complete!

Problem: locking decreases performance

Single-threaded counter:	3.850 seconds
Multi-threaded no-lock counter:	4.700 seconds (Broken!)
Naïve-locked counter:	80.000 seconds
Big lock counter:	3.895 seconds
Sloppy lock (synchronize every 100):	2.150 seconds
Sloppy lock (synchronize every 10000):	1.472 seconds
Sloppy lock (synchronize every 1000000):	1.478 seconds
Sloppy lock (synchronize every 1000000000):	1.500 seconds

- Optimal for this counter example will be synchronizing once, when entirely finished with the local sum

Outline

- Applying Locks
- **Concurrent Data Structures**
- Ordering with Condition Variables
- Semaphores

Thread-safe data structures

- "Thread safe" – works even if used by multiple threads concurrently
  - Can apply to various libraries, functions, and data structures

- Simple data structures implementations are usually not thread safe
  - Some global state needs to be shared among all threads
  - Need to protect critical sections

- Challenge: multiple function calls each access same shared structure
  - Need to identify the critical section in each and lock it with shared lock

Linked List

```
void List_Insert(list_t *L, int key) {
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    return; // fail
  }
  new->key = key;
  new->next = L->head;
  L->head = new;
  return; // success
}
```

Concurrent Linked List – Big lock approach

```
void List_Insert(list_t *L, int key) {
  pthread_mutex_lock(&L->lock);
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    pthread_mutex_unlock(&L->lock);
    return; // fail
  }
  new->key = key;
  new->next = L->head;
  L->head = new;
  pthread_mutex_unlock(&L->lock);
  return; // success
}
```

Most important part of this example. Don't forget to unlock if returning early.

- Much better than counter example, because we are only serializing the list itself. Hopefully the rest of the code can run concurrently.

Better Concurrent Linked List – Only lock critical section

```
void List_Insert(list_t *L, int key) {
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    return; // fail
  }
  new->key = key;
  new->next = L->head;
  L->head = new;
  return; // success
}
```

Check your understanding:

Where is the critical section here?

Better Concurrent Linked List – Only lock critical section

```
void List_Insert(list_t *L, int key) {
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    return; // fail
  }
  new->key = key;
  new->next = L->head;
  L->head = new;
  return; // success
}
```

Check your understanding:

Where is the critical section here?

What about malloc? Is that safe to use??

```
void List_Insert(list_t *L, int key) {
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    return; // fail
  }
  new->key = key;
  new->next = L->head;
  L->head = new;
  return; // success
}
```

- Thread-safe functions
  - Capable of being called concurrently and still functioning correctly
  - (Because they use locks!)
- How would we know if malloc is thread-safe?

Must check the library documentation to determine thread safety

- https://man7.org/linux/man-pages/man3/malloc.3.html

- Malloc (and free) is indeed thread-safe

ATTRIBUTES top

For an explanation of the terms used in this section, see attributes(7).

Interface	Attribute	Value
malloc(), **free**(), **calloc**(), **realloc**()	Thread safety	MT-Safe

- If it wasn't, we would have to consider it another shared resource that needs to be locked

Better Concurrent Linked List – Only lock critical section

```
void List_Insert(list_t *L, int key) {
  node_t *new = malloc(sizeof(node_t));
  if (new == NULL) {
    perror("malloc");
    return; // fail
  }
  new->key = key;
  pthread_mutex_lock(&L->lock);
  new->next = L->head;
  L->head = new;
  pthread_mutex_unlock(&L->lock);
  return; // success
}
```

- Now new node is created locally in parallel
- Only actual access to the linked list is serialized

Concurrent Queue

- Separate head & tail locks
- Allows concurrent add & remove
  - Up to 2 threads can access without waiting

```
1   typedef struct __node_t {
2       int                 value;
3       struct __node_t    *next;
4   } node_t;
5
6   typedef struct __queue_t {
7       node_t             *head;
8       node_t             *tail;
9       pthread_mutex_t     headLock;
10      pthread_mutex_t     tailLock;
11  } queue_t;
12
13  void Queue_Init(queue_t *q) {
14      node_t *tmp = malloc(sizeof(node_t));
15      tmp->next = NULL;
16      q->head = q->tail = tmp;
17      pthread_mutex_init(&q->headLock, NULL);
18      pthread_mutex_init(&q->tailLock, NULL);
19  }
```

```
21  void Queue_Enqueue(queue_t *q, int value) {
22      node_t *tmp = malloc(sizeof(node_t));
23      assert(tmp != NULL);
24      tmp->value = value;
25      tmp->next  = NULL;
26
27      pthread_mutex_lock(&q->tailLock);
28      q->tail->next = tmp;
29      q->tail = tmp;
30      pthread_mutex_unlock(&q->tailLock);
31  }
32
33  int Queue_Dequeue(queue_t *q, int *value) {
34      pthread_mutex_lock(&q->headLock);
35      node_t *tmp = q->head;
36      node_t *newHead = tmp->next;
37      if (newHead == NULL) {
38          pthread_mutex_unlock(&q->headLock);
39          return -1; // queue was empty
40      }
41      *value = newHead->value;
42      q->head = newHead;
43      pthread_mutex_unlock(&q->headLock);
44      free(tmp);
45      return 0;
46  }
```

Concurrent Queue

- "tailLock" controls adding elements
- Looks similar to ListInsert

```
1   typedef struct __node_t {
2       int                 value;
3       struct __node_t    *next;
4   } node_t;
5
6   typedef struct __queue_t {
7       node_t             *head;
8       node_t             *tail;
9       pthread_mutex_t     headLock;
10      pthread_mutex_t     tailLock;
11  } queue_t;
12
13  void Queue_Init(queue_t *q) {
14      node_t *tmp = malloc(sizeof(node_t));
15      tmp->next = NULL;
16      q->head = q->tail = tmp;
17      pthread_mutex_init(&q->headLock, NULL);
18      pthread_mutex_init(&q->tailLock, NULL);
19  }
```

```
21  void Queue_Enqueue(queue_t *q, int value) {
22      node_t *tmp = malloc(sizeof(node_t));
23      assert(tmp != NULL);
24      tmp->value = value;
25      tmp->next  = NULL;
26
27      pthread_mutex_lock(&q->tailLock);
28      q->tail->next = tmp;
29      q->tail = tmp;
30      pthread_mutex_unlock(&q->tailLock);
31  }
32
33  int Queue_Dequeue(queue_t *q, int *value) {
34      pthread_mutex_lock(&q->headLock);
35      node_t *tmp = q->head;
36      node_t *newHead = tmp->next;
37      if (newHead == NULL) {
38          pthread_mutex_unlock(&q->headLock);
39          return -1; // queue was empty
40      }
41      *value = newHead->value;
42      q->head = newHead;
43      pthread_mutex_unlock(&q->headLock);
44      free(tmp);
45      return 0;
46  }
```

Concurrent Queue

- Head lock controls removing elements from front
- Needs to lock almost entire function

```
1   typedef struct __node_t {
2       int                 value;
3       struct __node_t    *next;
4   } node_t;
5
6   typedef struct __queue_t {
7       node_t             *head;
8       node_t             *tail;
9       pthread_mutex_t     headLock;
10      pthread_mutex_t     tailLock;
11  } queue_t;
12
13  void Queue_Init(queue_t *q) {
14      node_t *tmp = malloc(sizeof(node_t));
15      tmp->next = NULL;
16      q->head = q->tail = tmp;
17      pthread_mutex_init(&q->headLock, NULL);
18      pthread_mutex_init(&q->tailLock, NULL);
19  }
```

```
21  void Queue_Enqueue(queue_t *q, int value) {
22      node_t *tmp = malloc(sizeof(node_t));
23      assert(tmp != NULL);
24      tmp->value = value;
25      tmp->next  = NULL;
26
27      pthread_mutex_lock(&q->tailLock);
28      q->tail->next = tmp;
29      q->tail = tmp;
30      pthread_mutex_unlock(&q->tailLock);
31  }
32
33  int Queue_Dequeue(queue_t *q, int *value) {
34      pthread_mutex_lock(&q->headLock);
35      node_t *tmp = q->head;
36      node_t *newHead = tmp->next;
37      if (newHead == NULL) {
38          pthread_mutex_unlock(&q->headLock);
39          return -1; // queue was empty
40      }
41      *value = newHead->value;
42      q->head = newHead;
43      pthread_mutex_unlock(&q->headLock);
44      free(tmp);
45      return 0;
46  }
```

Concurrent Hash Table

- Each bucket is implemented with a Concurrent List
  - We don't have to define any locks!
  - (Locks are in the lists)
- A thread can access a bucket without blocking other threads' access to ***other*** buckets.
- Hash tables are ideal for concurrency.
  - Hash (bucket id) can be calculated without accessing a shared resource.
  - ***Distributed hash tables*** are used for huge NoSQL databases.

```
1   #define BUCKETS (101)
2
3   typedef struct __hash_t {
4       list_t lists[BUCKETS];
5   } hash_t;
6
7   void Hash_Init(hash_t *H) {
8       int i;
9       for (i = 0; i < BUCKETS; i++) {
10          List_Init(&H->lists[i]);
11      }
12  }
13
14  int Hash_Insert(hash_t *H, int key) {
15      int bucket = key % BUCKETS;
16      return List_Insert(&H->lists[bucket], key);
17  }
18
19  int Hash_Lookup(hash_t *H, int key) {
20      int bucket = key % BUCKETS;
21      return List_Lookup(&H->lists[bucket], key);
22  }
```

Lock-free data structures

- In our original example, we put a lock around `counter++`
  - We could have instead used `atomic_fetch_and_add` to update counter
  - Lock-free and *still* atomic!!

- This is possible with more complex data structures as well
  - Often based on a compare-and-swap (CAS) approach
  - https://www.cs.cmu.edu/~410-s05/lectures/L31_LockFree.pdf

- Warning: these are not to be taken lightly
  - Atomic instructions have performance costs on processors
  - Getting this correct involves really understanding hardware
  - https://abseil.io/docs/cpp/atomic_danger

Break + Question: Where is the critical section for vector?

```
typedef struct {
  size_t size;
  size_t count;
  int** data;
} vector_t;

void vector_add(vector_t* v, int* item) {
  if (v->count == v->size) {
    v->size *= 2;
    v->data = realloc(v->data, sizeof(int*)*v->size);
  }
  v->data[v->count++] = item;
}
```

Break + Question: Where is the critical section for vector?

```
typedef struct {
  size_t size;
  size_t count;
  int** data;
} vector_t;

void vector_add(vector_t* v, int* item) {
  if (v->count == v->size) {
    v->size *= 2;
    v->data = realloc(v->data, sizeof(int*)*v->size);
  }
  v->data[v->count++] = item;
}
```

Outline

- Applying Locks
- Concurrent Data Structures
- **Ordering with Condition Variables**
- Semaphores

Requirements for sensible concurrency

- **Mutual exclusion**
  - Prevents corruption of data manipulated in critical sections
  - Atomic instructions → Locks → Concurrent data structures

- **Ordering** (B runs after A)
  - By default, concurrency leads to a lack of control over ordering
  - We can use mutex'd variables to control ordering, but it's inefficient:
    - `while(!myTurn) sleep(1);`

  - We would like cooperating threads to be able to signal each other.
    - Park/unpark and futex could be used solve this problem
    - But we want a higher-level abstraction

Barriers for all-or-nothing synchronization

- Barriers create synchronization points in the program
  - **All** threads must reach barrier before **any** thread continues

- pthread_barrier_init(barrier_t)
- pthread_barrier_wait(barrier_t)

- Use case: neural network processing
  - Spawn a pool of threads
  - Each thread handles a portion of the input data
  - Collect results from all threads at the end of the layer
  - Distribute results to appropriate threads for next layer

Basic Signaling with Condition Variable (condvar)

- Queue of waiting threads
  - Combine with a **flag** and a **mutex** to synchronize threads

- wait(condvar_t, lock_t)
  - Lock must be held when wait() is called
  - Puts the caller to sleep and releases lock (atomically)
  - When awoken, reacquires lock before returning

- signal(condvar_t)
  - Wake a single waiting thread (if any are waiting)
  - Do nothing if there are no waiting threads
  - Called while holding the lock; takes the action after lock is released

Waiting for a thread to finish

```
pthread_t p1, p2;

// create child threads
pthread_create(&p1, NULL, mythread, "A");
pthread_create(&p2, NULL, mythread, "B");

...

// join waits for the child threads to finish
thr_join(p1, NULL);
thr_join(p2, NULL);

return 0;
```

How to implement join?

CV for child wait

- Must use mutex to protect "done" flag and condvar

```
1  int done  = 0;
2  pthread_mutex_t m = PTHREAD_MUTEX_INITIALIZER;
3  pthread_cond_t c  = PTHREAD_COND_INITIALIZER;
4
5  void thr_exit() {
6      Pthread_mutex_lock(&m);
7      done = 1;
8      Pthread_cond_signal(&c);
9      Pthread_mutex_unlock(&m);
10 }
11
12 void *child(void *arg) {
13     printf("child\n");
14     thr_exit();
15     return NULL;
16 }
17
18 void thr_join() {
19     Pthread_mutex_lock(&m);
20     while (done == 0)
21         Pthread_cond_wait(&c, &m);
22     Pthread_mutex_unlock(&m);
23 }
24
25 int main(int argc, char *argv[]) {
26     printf("parent: begin\n");
27     pthread_t p;
28     Pthread_create(&p, NULL, child, NULL);
29     thr_join();
30     printf("parent: end\n");
31     return 0;
32 }
```

CV for child wait

- Must use mutex to protect "done" flag and condvar

- **Parent** calls thr_join()
  - wait()'s until done==1

```
1  int done  = 0;
2  pthread_mutex_t m = PTHREAD_MUTEX_INITIALIZER;
3  pthread_cond_t c  = PTHREAD_COND_INITIALIZER;
4
5  void thr_exit() {
6      Pthread_mutex_lock(&m);
7      done = 1;
8      Pthread_cond_signal(&c);
9      Pthread_mutex_unlock(&m);
10 }
11
12 void *child(void *arg) {
13     printf("child\n");
14     thr_exit();
15     return NULL;
16 }
17
18 void thr_join() {
19     Pthread_mutex_lock(&m);
20     while (done == 0)
21         Pthread_cond_wait(&c, &m);
22     Pthread_mutex_unlock(&m);
23 }
24
25 int main(int argc, char *argv[]) {
26     printf("parent: begin\n");
27     pthread_t p;
28     Pthread_create(&p, NULL, child, NULL);
29     thr_join();
30     printf("parent: end\n");
31     return 0;
32 }
```

CV for child wait

- Must use mutex to protect "done" flag and condvar

- **Parent** calls thr_join()
  - wait()'s until done==1

- **Child** calls thr_exit()
  - sets done to 1
  - calls signal()
  - unlocks mutex

```
1  int done  = 0;
2  pthread_mutex_t m = PTHREAD_MUTEX_INITIALIZER;
3  pthread_cond_t c  = PTHREAD_COND_INITIALIZER;
4
5  void thr_exit() {
6      Pthread_mutex_lock(&m);
7      done = 1;
8      Pthread_cond_signal(&c);
9      Pthread_mutex_unlock(&m);
10 }
11
12 void *child(void *arg) {
13     printf("child\n");
14     thr_exit();
15     return NULL;
16 }
17
18 void thr_join() {
19     Pthread_mutex_lock(&m);
20     while (done == 0)
21         Pthread_cond_wait(&c, &m);
22     Pthread_mutex_unlock(&m);
23 }
24
25 int main(int argc, char *argv[]) {
26     printf("parent: begin\n");
27     pthread_t p;
28     Pthread_create(&p, NULL, child, NULL);
29     thr_join();
30     printf("parent: end\n");
31     return 0;
32 }
```

Buggy attempts to wait for a child, no flag

Incorrect Code

Child

```
1   void thr_exit() {
2       Pthread_mutex_lock(&m);
3       Pthread_cond_signal(&c);
4       Pthread_mutex_unlock(&m);
5   }
6
```

Parent

```
7   void thr_join() {
8       Pthread_mutex_lock(&m);
9       Pthread_cond_wait(&c, &m);
10      Pthread_mutex_unlock(&m);
11  }
```

Correct Code

```
5   void thr_exit() {
6       Pthread_mutex_lock(&m);
7       done = 1;
8       Pthread_cond_signal(&c);
9       Pthread_mutex_unlock(&m);
10  }
18  void thr_join() {
19      Pthread_mutex_lock(&m);
20      while (done == 0)
21          Pthread_cond_wait(&c, &m);
22      Pthread_mutex_unlock(&m);
23  }
```

1) Without *done* variable, the child could run first and signal before the parent starts waiting for the child.

Buggy attempts to wait for a child, no mutex

Incorrect Code

Child

```
1   void thr_exit() {
2       done = 1;
3       Pthread_cond_signal(&c);
4   }
```

Parent

```
5
6   void thr_join() {
7       if (done == 0)
8           Pthread_cond_wait(&c);
9   }
```

Correct Code

```
5   void thr_exit() {
6       Pthread_mutex_lock(&m);
7       done = 1;
8       Pthread_cond_signal(&c);
9       Pthread_mutex_unlock(&m);
10  }
18  void thr_join() {
19      Pthread_mutex_lock(&m);
20      while (done == 0)
21          Pthread_cond_wait(&c, &m);
22      Pthread_mutex_unlock(&m);
23  }
```

2) Without a lock, the parent could see done==0,
then the child could finish and signal,
then the parent would start waiting (after missing the signal).

Spurious (fake) wakeups

- Pthreads allows wakeup to return not just when a signaled, but also when a ***timer expires*** or for ***no reason at all!***
- Spurious wakeups were included in the specification because they may allow some implementations be more efficient.
- There is no guarantee that the condition you've been waiting for is true when you are awoken
- So, we must also use a "predicate loop." (*while*, not *if*)

```
1   int done  = 0;
2   pthread_mutex_t m = PTHREAD_MUTEX_INITIALIZER;
3   pthread_cond_t c  = PTHREAD_COND_INITIALIZER;
4
5   void thr_exit() {
6       Pthread_mutex_lock(&m);
7       done = 1;
8       Pthread_cond_signal(&c);
9       Pthread_mutex_unlock(&m);
10  }
11
12  void *child(void *arg) {
13      printf("child\n");
14      thr_exit();
15      return NULL;
16  }
17
18  void thr_join() {
19      Pthread_mutex_lock(&m);
20      while (done == 0)
21          Pthread_cond_wait(&c, &m);
22      Pthread_mutex_unlock(&m);
23  }
24
25  int main(int argc, char *argv[]) {
26      printf("parent: begin\n");
27      pthread_t p;
28      Pthread_create(&p, NULL, child, NULL);
29      thr_join();
30      printf("parent: end\n");
31      return 0;
32  }
```

Another Example: Produce/Consumer Problem

- We have multiple producers and multiple consumers that communicate with a shared queue (FIFO buffer).
  - Concurrent queue allows work to happen asynchronously.
  - Buffer has finite size (does not dynamically expand)

- Two operations:
  - ***Put***, which should block (wait) if the buffer is **full**.
  - ***Get***, which should block (wait) if the buffer is **empty**.

- This is more complex than a (linked-list-based) concurrent queue because of the finite size and waiting.
- Example scenario: request queue in a multi-threaded web server.

Managing the buffer

```
1   int buffer[MAX];
2   int fill  = 0;
3   int use   = 0;
4   int count = 0;
5
6   void put(int value) {
7       buffer[fill] = value;
8       fill = (fill + 1) % MAX;
9       count++;
10  }
11
12  int get() {
13      int tmp = buffer[use];
14      use = (use + 1) % MAX;
15      count--;
16      return tmp;
17  }
```

- A simple implementation of a circular buffer that stores data in a fixed-size array.
- ***fill*** is the index of the tail
- ***use*** is the index of the head
- ***count*** = **`(fill - use) % MAX`**

This simple implementation assumes:

- Concurrency is managed elsewhere
- It will overwrite data if we try to put more than MAX elements.

Managing the concurrency

```
1   cond_t empty, fill;
2   mutex_t mutex;
3
4   void *producer(void *arg) {
5       int i;
6       for (i = 0; i < loops; i++) {
7           Pthread_mutex_lock(&mutex);
8           while (count == MAX)
9               Pthread_cond_wait(&empty, &mutex);
10          put(i);
11          Pthread_cond_signal(&fill);
12          Pthread_mutex_unlock(&mutex);
13      }
14  }
15
16  void *consumer(void *arg) {
17      int i;
18      for (i = 0; i < loops; i++) {
19          Pthread_mutex_lock(&mutex);
20          while (count == 0)
21              Pthread_cond_wait(&fill, &mutex);
22          int tmp = get();
23          Pthread_cond_signal(&empty);
24          Pthread_mutex_unlock(&mutex);
25          printf("%d\n", tmp);
26      }
27  }
```

- Always acquire ***mutex***
  - Must use same mutex in both functions
- Use ***two condvars***

Managing the concurrency

```
1   cond_t empty, fill;
2   mutex_t mutex;
3
4   void *producer(void *arg) {
5       int i;
6       for (i = 0; i < loops; i++) {
7           Pthread_mutex_lock(&mutex);
8           while (count == MAX)
9               Pthread_cond_wait(&empty, &mutex);
10          put(i);
11          Pthread_cond_signal(&fill);
12          Pthread_mutex_unlock(&mutex);
13      }
14  }
15
16  void *consumer(void *arg) {
17      int i;
18      for (i = 0; i < loops; i++) {
19          Pthread_mutex_lock(&mutex);
20          while (count == 0)
21              Pthread_cond_wait(&fill, &mutex);
22          int tmp = get();
23          Pthread_cond_signal(&empty);
24          Pthread_mutex_unlock(&mutex);
25          printf("%d\n", tmp);
26      }
27  }
```

- Always acquire ***mutex***
  - Must use same mutex in both functions
- Use ***two condvars***

- Producer waits on **empty** while the buffer is full
  - Producer signals **fill** after `put`

Managing the concurrency

```
1   cond_t empty, fill;
2   mutex_t mutex;
3
4   void *producer(void *arg) {
5       int i;
6       for (i = 0; i < loops; i++) {
7           Pthread_mutex_lock(&mutex);
8           while (count == MAX)
9               Pthread_cond_wait(&empty, &mutex);
10          put(i);
11          Pthread_cond_signal(&fill);
12          Pthread_mutex_unlock(&mutex);
13      }
14  }
15
16  void *consumer(void *arg) {
17      int i;
18      for (i = 0; i < loops; i++) {
19          Pthread_mutex_lock(&mutex);
20          while (count == 0)
21              Pthread_cond_wait(&fill, &mutex);
22          int tmp = get();
23          Pthread_cond_signal(&empty);
24          Pthread_mutex_unlock(&mutex);
25          printf("%d\n", tmp);
26      }
27  }
```

- Always acquire ***mutex***
  - Must use same mutex in both functions
- Use ***two condvars***

- Producer waits on **empty** while the buffer is full
  - Producer signals **fill** after `put`

- Consumer waits on **fill** while the buffer is empty
  - Consumer signals empty after `get`

Managing the concurrency

```
1   cond_t empty, fill;
2   mutex_t mutex;
3
4   void *producer(void *arg) {
5       int i;
6       for (i = 0; i < loops; i++) {
7           Pthread_mutex_lock(&mutex);
8           while (count == MAX)
9               Pthread_cond_wait(&empty, &mutex);
10          put(i);
11          Pthread_cond_signal(&fill);
12          Pthread_mutex_unlock(&mutex);
13      }
14  }
15
16  void *consumer(void *arg) {
17      int i;
18      for (i = 0; i < loops; i++) {
19          Pthread_mutex_lock(&mutex);
20          while (count == 0)
21              Pthread_cond_wait(&fill, &mutex);
22          int tmp = get();
23          Pthread_cond_signal(&empty);
24          Pthread_mutex_unlock(&mutex);
25          printf("%d\n", tmp);
26      }
27  }
```

- Always acquire ***mutex***
  - Must use same mutex in both functions
- Use ***two condvars***

- Producer waits on **empty** while the buffer is full
  - Producer signals **fill** after `put`

- Consumer waits on **fill** while the buffer is empty
  - Consumer signals empty after `get`

- Loops re-check count condition after breaking out of wait, to handle spurious wakeups.

Broadcast makes more complex conditions possible

- Recall that *signal* wakes one waiting thread (FIFO)
  - But there are times when threads are not all equivalent
  - The signal may not be serviceable by any of the threads

- For example, consider memory allocation/free requests
  - An allocation can only be serviced by free of >= size

- `pthread_cond_broadcast` wakes all threads
  - This approach may be inefficient, but it may be necessary to ensure progress

Condition Variable: rules of thumb

- Shared state determines if condition is true or not
  - Check the state in a while loop before waiting on condvar
- Use a mutex to protect:
  - The shared state on which condition is based, and
  - Operations on the condvar
- Remember to acquire the mutex before calling **`cond_signal()`** and **`cond_broadcast()`**
- Use different condvars for different conditions
  - Sometimes, **`cond_broadcast()`** helps if you can't find an elegant solution using **`cond_signal()`**

Break + Administrivia

- Get started on PCLab
  - Hard part isn't the implementation, but the *debugging*
  - PCLab discussion on Friday

- Midterm exam is coming soon!
  - Two weeks from now
  - We'll have a review session during discussion next week Friday
  - I'll distribute a practice exam as well

Outline

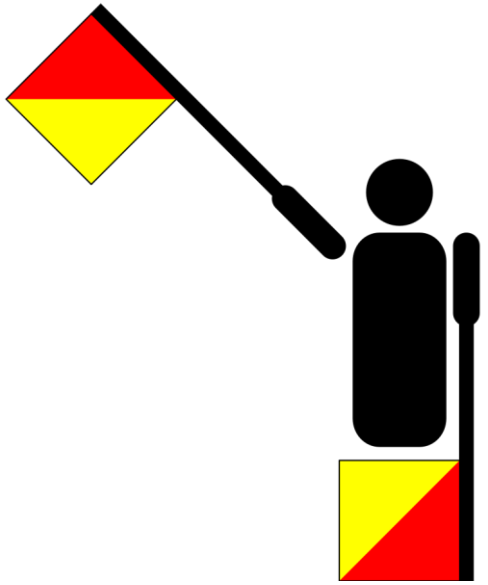
- Applying Locks
- Concurrent Data Structures
- Ordering with Condition Variables
- **Semaphores**

Generalizing Synchronization

- Condvars have no state or lock, just a waiting queue
  - The rest is handled by the programmer

- Semaphores are a generalization of condvars and locks
  - Includes internal (locked) state
  - A little harder to understand and use, but can do everything

Semaphores (by Edsger Dijkstra, 1965)



- Keeps an internal integer value that determines what happens to a calling thread

- Init(val)
  - Set the initial internal value
  - Value cannot otherwise be directly modified

- Up/Signal/Post/V() (from Dutch *verhogen* "increase")
  - Increase the value. If there is a waiting thread, wake one.

- Down/Wait/Test/P() (from Dutch *proberen* "to try")
  - Decrease the value. Wait if the value is negative.

Dijkstra invented Dijkstra's Algorithm!

Also Semaphores and the entire field of Concurrent Programming

https://en.wikipedia.org/wiki/Edsger_W._Dijkstra

Semaphores vs Condition Variables

- Semaphores
- ***Up/Post***: increase value and wake one waiting thread
- ***Down/Wait***: decrease value and wait if it's negative

- Condition Variables
- ***Signal***: wake one waiting thread
- ***Wait***: wait

- Compared to CVs, Semaphores add an integer value that controls when waiting is necessary
  - Value counts the quantity of a shared resource currently available
  - *Up* makes a resource available, *down* reserves a resource
  - Negative value **-X** means that **X** threads are waiting for the resource

Check your understanding

- How would we build a mutex out of a semaphore?

```
typdef struct {
  sem_t sem;
} lock_t;
init(lock_t* lock){

}
acquire(lock_t* lock) {

}
release(lock_t* lock) {

}
```

```
sem_init(sem_t*, int initial)
sem_wait(sem_t*): Decrement, wait until
                  value >= 0
sem_post(sem_t*): Increment value then
                  wake a single waiter
```

Check your understanding

- How would we build a mutex out of a semaphore?

```
typdef struct {
  sem_t sem;
} lock_t;
init(lock_t* lock){
  sem_init(&(lock->sem), 1);
}
acquire(lock_t* lock) {
  sem_wait(&(lock->sem));
}
release(lock_t* lock) {
  sem_post(&(lock->sem));
}
```

```
sem_init(sem_t*, int initial)
sem_wait(sem_t*): Decrement, wait until
                  value >= 0
sem_post(sem_t*): Increment value then
                  wake a single waiter
```

Implementing a lock with a semaphore

- Choose an appropriate initial value for the semaphore
- To implement a ***Lock:***
  - Initialize to 1 (access to the critical section is the one shared resource)
  - **Lock** → **Down**: (decreases the value and waits if negative)
    - Will decrease the value to 0 if it lock *is not* already taken
    - Will decrease the value to -1 and wait if the lock *is* taken (value was 0)
  - **Unlock** → **Up**: (increases the value and wakes one waiting thread)
    - If value was 0, then no thread was waiting, and no thread is woken
    - If value was -1, then one thread was waiting, and it is woken
    - If value was -x, then x threads are waiting, one is woken, value becomes -(x-1).
  - If value is already 1, *Up* should not be called. (Unlock before lock?!)

Semaphores reduce effort for numerical conditions

Condition Variable

Child

```
5   void thr_exit() {
6       Pthread_mutex_lock(&m);
7       done = 1;
8       Pthread_cond_signal(&c);
9       Pthread_mutex_unlock(&m);
10  }
```

Parent

```
18  void thr_join() {
19      Pthread_mutex_lock(&m);
20      while (done == 0)
21          Pthread_cond_wait(&c, &m);
22      Pthread_mutex_unlock(&m);
23  }
```

Semaphore

```
void thr_exit() {
    sem_post(&s);
}

void thr_join() {
    sem_wait(&s);
}

sem_init(&s, 0);
```

- Want parent to wait immediately so initialize to 0
- If child thread finishes first, semaphore increments to 1

Readers-Writers Problem

- Some resources don't need strict mutual exclusion, especially if they have many ***read-only*** accesses. (eg., a linked list)

- Any number of readers can be active simultaneously, but
- Writes must be mutually exclusive AND cannot happen during read

- API:
  - acquire_read_lock(), release_read_lock()
  - acquire_write_lock(), release_write_lock()

Reader-writer Lock

- "lock" semaphore used as a mutex

```
1   typedef struct _rwlock_t {
2     sem_t lock;      // binary semaphore (basic lock)
3     sem_t writelock; // used to allow ONE writer or MANY readers
4     int   readers;   // count of readers reading in critical section
5   } rwlock_t;
6
7   void rwlock_init(rwlock_t *rw) {
8     rw->readers = 0;
9     sem_init(&rw->lock, 0, 1);
10    sem_init(&rw->writelock, 0, 1);
11  }
12
13  void rwlock_acquire_readlock(rwlock_t *rw) {
14    sem_wait(&rw->lock);
15    rw->readers++;
16    if (rw->readers == 1)
17      sem_wait(&rw->writelock); // first reader acquires writelock
18    sem_post(&rw->lock);
19  }
20
21  void rwlock_release_readlock(rwlock_t *rw) {
22    sem_wait(&rw->lock);
23    rw->readers--;
24    if (rw->readers == 0)
25      sem_post(&rw->writelock); // last reader releases writelock
26    sem_post(&rw->lock);
27  }
28
29  void rwlock_acquire_writelock(rwlock_t *rw) {
30    sem_wait(&rw->writelock);
31  }
32
33  void rwlock_release_writelock(rwlock_t *rw) {
34    sem_post(&rw->writelock);
35  }
```

Reader-writer Lock

- "writelock" must be held during read to block writes or during write to block reads.

- During reads
  - Number of active readers is counted.
  - First/last reader handles acquiring/releasing writelock.

```
1   typedef struct _rwlock_t {
2     sem_t lock;      // binary semaphore (basic lock)
3     sem_t writelock; // used to allow ONE writer or MANY readers
4     int   readers;   // count of readers reading in critical section
5   } rwlock_t;
6
7   void rwlock_init(rwlock_t *rw) {
8     rw->readers = 0;
9     sem_init(&rw->lock, 0, 1);
10    sem_init(&rw->writelock, 0, 1);
11  }
12
13  void rwlock_acquire_readlock(rwlock_t *rw) {
14    sem_wait(&rw->lock);
15    rw->readers++;
16    if (rw->readers == 1)
17      sem_wait(&rw->writelock); // first reader acquires writelock
18    sem_post(&rw->lock);
19  }
20
21  void rwlock_release_readlock(rwlock_t *rw) {
22    sem_wait(&rw->lock);
23    rw->readers--;
24    if (rw->readers == 0)
25      sem_post(&rw->writelock); // last reader releases writelock
26    sem_post(&rw->lock);
27  }
28
29  void rwlock_acquire_writelock(rwlock_t *rw) {
30    sem_wait(&rw->writelock);
31  }
32
33  void rwlock_release_writelock(rwlock_t *rw) {
34    sem_post(&rw->writelock);
35  }
```

Classical concurrency problems

- Note that this solution could starve writers
  - There might always be readers in the critical section

- Full solution to readers-writers problem with progress guarantee
  - https://en.wikipedia.org/wiki/Readers%E2%80%93writers_problem

- Generally: try to map your problem to one of these solved problems
  - Producers/Consumers
  - Readers/Writers

Outline

- Applying Locks
